The present invention generally relates to microprocessor design, and more specifically to a methodology and system to optimize the microprocessor design. Microprocessors perform a variety of tasks and algorithms, such as arithmetic, logic, and control. For example, microprocessors are used in applications such as microcontrollers, personal computers, embedded systems, etc. In general, a microprocessor has a plurality of functions that perform basic operations such as adding or subtracting numbers, performing logic functions, or controlling the flow of data. Typically, a microprocessor is designed using a specification language, such as VHDL. The specification language specifies the individual functions that can be used by the microprocessor and the circuits that perform these functions. Once the specification language is defined, the designers define the circuit using a design environment, such as Design Architect™ from Altera Corporation. The system description is then simulated in the design environment to verify functionality. The simulation is usually performed at the register transfer level (RTL), which is a language level that describes what is happening on the circuit. Once the RTL simulation has
